#### Abstract

This paper presents tha **Zebende**, a Python package written in Python and Zig, that calculates the DFA, DCCA  $\rho_{DCCA}$  and the  $DMC_x^2$ . The package presents an optimized algorithm that significantly improves the calculations speed. A comparison with other packages that calculates the .The package is also the first to implement the  $DMC_x^2$  coefficient for any number of series.

Keywords:  $\rho_{DCCA}$ ,  $DMC_x^2$ , optimization, Python, Zig.

#### 1. introduction

The  $\rho_{DCCA}$  (Zebende 2011) is a widely used coefficient that measures the cross-correlation between tow non-stationary time series. It's an extension of the Detrended Fluctuation Analysis (DFA) (Peng, Buldyrev, Havlin, Simons, Stanley, and Goldberger 1994) and the Detrended Cross-correlation Analysis (DCCA) (Podobnik and Stanley 2008): while the DFA calculates the self-affinity and long-memory properties of a time series data, and the DCCA analyses power-law cross correlations between two different non-stationarity time series, the  $\rho_{DCCA}$  coefficient quantifies this cross-correlation in simple values ranging from -1 to 1, where -1 indicates a perfect anti-correlation between the series, 1 a perfect correlation and zero (0) no correlation at all.

The Detrended Multiple Cross-Correlation Coefficient (Zebende and Silva 2018)  $(DMC_x^2)$  is a generalization of the  $\rho_{DCCA}$  coefficient that correlates one time series (dependent variable) a number of time series (independent variables). The  $DMC_x^2$  values ranges from zero (0), indicating no correlation to 1, meaning perfect correlation or anti-correlation between the dependent and the independent variables.

This paper presents the **Zebende** Python package, an implementation of the DFA, DCCA,  $\rho_{DCCCA}$ ,  $DMC_x^2$  and utility functions related to the methods. In section 2 the steps for calculating the  $\rho_{DCCCA}$  and  $DMC_x^2$  are presented and discussed. Section 3 shows how this library was implemented, the optimization technics and the recommended steps to use the library. In Section 4 the **Zebende** package is compared with other packages for Python and R that calculates the  $\rho_{DCCA}$  in terms of performance and usability, leading to the conclusions in 5.

#### 2. Algorithms of the coefficients

The algorithms that calculates the  $\rho_{DCCA}$  uses the DFA and the DCCA steps. The  $DMC_x^2$  coefficient uses the  $\rho_{DCCA}$  coefficient and, consequently, also embraces the DFA and the DCCA. The DFA method is described in six steps:

- 1. Taking a time series  $\{x_i\}$  with i ranging from 1 to N, the integrated series  $X_k$  is calculated by  $X_k = \sum_{i=1}^k [x_i \langle x \rangle]$  with k also ranging from 1 to N;
- 2. the  $X_k$  series is divided in N-n boxes of size n(time scale), each box containing n+1 values, starting in i up to i+n;
- 3. for each box, a polynomial (usually of degree 1) best fit is calculated, getting  $\widetilde{X}_{k,i}$  with  $i \leq k \leq (i+n)$  (detrended values);
- 4. in each box is calculated:  $f_{DFA}^2(n,i) = \frac{1}{1+n} \sum_{k=i}^{i+n} (X_k \tilde{X}_{k,i})^2$
- 5. for all the boxes of a time scale, the DFA is calculated as:

$$F_{DFA}(n) = \sqrt{\frac{1}{N-n} \sum_{i=1}^{N-n} f_{DFA}^2(n,i)};$$

6. for a number of different timescales (n), with possible values  $4 \le n \le \frac{N}{4}$  the  $F_{DFA}$  function is calculated to find a relation among  $F_{DFA} \times n$ 

The DCCA method is very similar to the DFA calculations. With the difference of analyzing two series while the DFA evaluate properties of a single time series. It's also a six steps process:

- 1. Taking two time series with the same length  $\{x\alpha_i\}$  and  $\{x\beta_i\}$  with i ranging from 1 to N, the integrated series  $X\alpha_k$  and  $X\beta_k$  are calculated by  $X_k = \sum_{i=1}^k [x_i \langle x \rangle]$  for each series, with k also ranging from 1 to N;
- 2.  $X\alpha_k$  and  $X\beta_k$  series are divided in N-n boxes of size n(time scale), each box containing n+1 values, starting in i up to i+n;
- 3. for each box, a polynomial (usually of degree 1) best fit is calculated, getting  $\widetilde{X}\alpha_{k,i}$  and  $\widetilde{X}\widetilde{\beta}_{k,i}$ , for series  $\{x\alpha_i\}$  and  $\{x\beta_i\}$  respectively, with  $i \leq k \leq (i+n)$  (detrended values);
- 4. in each box is calculated:  $f_{DCCA}^2(n,i) = \frac{1}{1+n} \sum_{k=i}^{i+n} (X\alpha_k \widetilde{X\alpha}_{k,i}) \times (X\beta_k \widetilde{X\beta}_{k,i})$

5. for all the boxes of a time scale, the DCCA is calculated as:

$$F_{DCCA}^{2}(n) = \frac{1}{N-n} \sum_{i=1}^{N-n} f_{DCCA}^{2}(n,i);$$

6. for a number of different timescales (n), with possible values  $4 \le n \le \frac{N}{4}$  the  $F_{DCCA}^2$  function is calculated to find a relation among  $F_{DCCA}^2 \times n$ 

Comparing the algorithms, the first three are basically identical, the only difference is that the DCCA method apply those steps to two series. The step four of the DFA is essentially an application of the variance calculation and the equivalent step of the DCCA is a covariance between the two series. Step five calculates the square root of the mean of the variances calculated in in each box for the DFA, in the DCCA, the mean of the covariances calculated for each box is calculated in stead. The last step,in both cases, is more a reminder to repeat the respective previous operations for a number of difference time scales.

The  $\rho_{DCCA}$  is measured using Eq. 1. Considering the relation between DFA and variance and DCCA and covariance, the  $\rho_{DCCA}$  resembles Pearson correlation for a time scale n.

$$\rho_{DCCA}(n) = \frac{F_{DCCA (x\alpha, x\beta)}^2(n)}{F_{DFA (x\alpha)}(n) \times F_{DFA (x\beta)}(n)}$$
(1)

The  $DMC_x^2$  is a generalization of the  $\rho_{DCCA}$  that calculates the correlation between one time-series  $\{Y\}$ , as the dependent variable, and a number j of time-series  $\{X_1\}$ ,  $\{X_2\}$ ,  $\{X_3\}$ , ...,  $\{X_j\}$  defined as independent variables. The coefficient is expressed mathematically as:

$$DMC_x^2 \equiv \rho_{Y,X_i}(n)^T \times \rho^{-1}(n) \times \rho_{Y,X_i}(n)$$
(2)

In Eq. 2,  $\rho^{-1}(n)$  represent the inverse of a matrix populated by all possible combinations of  $\rho_{DCCA}$  between independent variables. In Eq. 3, value  $\rho_{X_1,X_2}(n)$ , for instance, is the  $\rho_{DCCA}$  for independent variables  $X_1$  and  $X_2$  calculated with time scale n, occupying position  $\rho_{12}$  of the matrix. Two fundamental characteristics: the first is that the main diagonal values are all ones, since it's position in the matrix denotes the calculation of a correlation between a series and itself. Second, the matrix is symmetric in relation to the main diagonal, as the  $\rho_{DCCA}$  is evaluated a commutative expression.

$$\rho^{-1}(n) = \begin{pmatrix} 1 & \rho_{X_1, X_2}(n) & \rho_{X_1, X_3}(n) & \dots & \rho_{X_1, X_j}(n) \\ \rho_{X_2, X_1}(n) & 1 & \rho_{X_2, X_3}(n) & \dots & \rho_{X_2, X_j}(n) \\ \vdots & \vdots & \vdots & \dots & \vdots \\ \rho_{X_j, X_1}(n) & \rho_{X_j, X_2}(n) & \rho_{X_j, X_3}(n) & \dots & 1 \end{pmatrix}^{-1}$$
(3)

At last Eq. 4 represent the transposed vector of the  $\rho_{Y,X_i}(n)$  between the depended variable  $\{Y\}$  and each  $\{X_i\}$  independent variable for a given time scale n.

$$\rho_{Y,X_i}(n)^T = [\rho_{Y,X_1}(n), \rho_{Y,X_2}(n), \cdots, \rho_{Y,X_i}(n)]$$
(4)

The  $\rho_{DCCA}$  and the  $DMC_x^2$  should be evaluated in a number of time scales (n) to analyze the characteristics of each coefficient.

## 3. Zebende package: implementation and optimization

The implementation of the Zebende package was focussed on some
